

Variables and Filters

Variables and filters serve for analysing subsets of the data and allows the users to statically or dynamically **modify content** of the report. It is feature, that makes filtering and drilling into the report very straightforward for report viewers. When **Filter** is set up to drill-down path, all **Views** including this **Drill-down** will be filtered according the definition.

BellaDati support many different types of filters and variables:

- **Report filters** - used to modify the content of the whole report. Multiple filters can be displayed in the sidebar or directly in the report as a special type of view. Each filter can have different functionality and appearance.
- **View filters** - used to modify the content of a single view (chart, table, map, etc.). The filters are displayed directly in the view in selected position. Each filter can have different functionality and appearance.
- **Variables** - used to dynamically load values into formulas and date intervals.
- **Static filters** - used to display only a subset of the data in the view. Users can modify these filters, but they are generally used as static filters which are configured during the setup of the report.
 - **Static View Filters** - filter is applied on the current view only, doesn't affect other views in the report
 - **Indicator Filters** - filter is applied on the desired indicator
